Helping the patient with pain

8: Changing opioids

Aim of this worksheet
To understand how to convert from one opioid to the other, looking at dose conversions and routes of administration

How to use this worksheet
- You can work through this worksheet by yourself, or with a tutor.
- Read the case study below, and then turn to the Work page overleaf.
- Work any way you want. You can start with the exercises on the Work page using your own knowledge. The answers are on the Information page - this is not cheating since you learn as you find the information. Alternatively you may prefer to start by reading the Information page before moving to the exercises on the Work page.
- This CLiP worksheet should take about 15 minutes to complete, but will take longer if you are working with colleagues or in a group. If anything is unclear, discuss it with a colleague.
- If you think any information is wrong or out of date let us know.
- Take this learning into your workplace using the activity on the back page.

Case study
Pat is a 36 year old woman, married with two sons aged 12 and 9. She had problems with her bowels for several months before some rectal bleeding made her see her GP. Investigations revealed a carcinoma of the sigmoid colon with liver metastases.
She has been troubled with nausea and vomiting and is finding it hard to keep her tablets down. She has been on oral morphine for several months, but is asking if it can be given any other way.
**Potency**

The potency of a drug tells you how strong the drug is in comparison with other similar drugs. A potent opioid will need less drug to give the same pain relief as higher doses of a weak opioid.

The opioids listed vary considerably in their potency:

- 3 strongest: fentanyl, buprenorphine and hydromorphone.
- 3 weakest: codeine, oral pethidine and tramadol.

Each preparation can be given in different ways:
- **oral (swallowed):** codeine, dihydrocodeine, morphine, dextromoramide, diamorphine, hydromorphone.
- **sublingual / buccal:** buprenorphine, fentanyl.
- **injection:** codeine, morphine, diamorphine, buprenorphine, fentanyl, hydromorphone (special order)
- **transdermal:** fentanyl, buprenorphine.

<table>
<thead>
<tr>
<th>Preparation</th>
<th>Conversion ratio from oral morphine</th>
<th>24 hour dose equivalent</th>
<th>12 hourly dose equivalent</th>
<th>4 hourly dose equivalent and 1/6th breakthrough dose*</th>
<th>10% of 24hr dose for breakthrough dose*</th>
</tr>
</thead>
<tbody>

<td>1mg</td>
</tr>
<tr>
<td>PO hydromorphone</td>
<td>+ 5</td>
<td>6mg</td>
<td>3mg</td>
<td>1mg (but 1.3mg is smallest oral dose available)</td>
<td>0.6mg (but 1.3mg is smallest oral dose available)</td>
</tr>
</tbody>
</table>

These conversions are approximations and the dose of the new opioid may have to be adjusted.

* Some teams are using 10% of the 24hr dose as a more cautious calculation for breakthrough doses

**30mg oral morphine/24hours**

\[
\text{= 300mg oral codeine / 24 hours [x 10] = 15mg subcutaneous diamorphine / 24 hours \left[\div 3\right]}
\]

\[
\text{= 20mg oral oxycodone / 24 hours \left[\div 1.5\right] = 6mg oral hydromorphone / 24 hours \left[\div 5\right]}
\]

For **TD fentanyl or buprenorphine**, use the manufacturers’ tables but the following can be used as a quick check:

**Total daily dose of oral morphine /day \left[\times 3\right] = dose of fentanyl or buprenorphine in microg/hour.**

For Pat, this works out as the equivalent of 20microg/hour TD opioid. This can be done by using a 25microg/hr fentanyl patch or a 20microg/hr buprenorphine patch.

**Choice of opioids for Pat**

Pat needs an opioid by a non-oral route that is at least as potent (since weaker opioids mean she would have to take a lot of the drug to have the same effect (eg. 60mg morphine = 600mg codeine)).

There are several opioids you might choose: morphine, diamorphine, oxycodone, hydromorphone, buprenorphine and fentanyl.

*Morphine and diamorphine* (UK only) are usually the first choices for parenteral use, and both can be given by subcutaneous infusion. Morphine injection is cheaper than diamorphine and units and teams are beginning to make it the first line parenteral strong opioid of choice.

*Oxycodone* injection is second line to morphine and diamorphine if the patients was already on oral oxycodone. The concentrated oxycodone injection is expensive.

*Hydromorphone* injection is a good alternative in countries where this is available and can also be given by subcutaneous infusion. It is only available in the UK as an import.

*Transdermal fentanyl or buprenorphine*: the time to reach a steady blood level is unpredictable, but can be as much as 14 hours. Consequently it is best not to give the last dose of controlled release opioid with the first patch, and cover any pain with instant-release preparations.

**Efficacy of opioids**

This defines how effective a drug is, regardless of dose. It is not the same as potency. For example, parenteral morphine is more potent than oral morphine, but it is not more effective. So, Pat’s pain would NOT be better relieved by changing to a more potent opioid or route.
Changing opioids would be easy IF all opioids had the same potency, range of adverse effects and were available by the same routes of administration. **Life is never that simple!** We will now look at changing doses and routes (for differences between opioids see CLiP worksheet 6 *Alternatives to Morphine*).

**Choose**

*From this list of oral opioids, choose the 3 strongest, and the 3 weakest* (the list is in alphabetical order, so no clue there!)

- buprenorphine
- codeine
- dextromoramide
- diamorphine
- dihydrocodeine
- fentanyl
- hydromorphone
- morphine
- oral pethidine
- tramadol

<table>
<thead>
<tr>
<th>3 strongest</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>3 weakest</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
</tr>
</tbody>
</table>

**Write**

*Next to the list above, write the routes of administration available*

- O = oral,  SL = sublingual,  I = injection (subcutaneous, intravenous, or intramuscular)  D = transdermal

**Calculate**

*Pat is on 60mg of morphine daily*

Check the table opposite and write in the equivalent daily dose of other opioids.

<table>
<thead>
<tr>
<th>Opioid</th>
<th>Dose per day</th>
</tr>
</thead>
<tbody>
<tr>
<td>codeine (oral)</td>
<td>mg</td>
</tr>
<tr>
<td>oxycodone (oral)</td>
<td>mg</td>
</tr>
<tr>
<td>diamorphine (subcutaneous)</td>
<td>mg</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Opioid</th>
<th>Dose per day</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hydromorphone (oral)</td>
<td>mg</td>
</tr>
<tr>
<td>fentanyl (transdermal)</td>
<td>microg/hr</td>
</tr>
</tbody>
</table>

**Reflect**

Now think about the available routes of administration for these opioids. Which opioids could you use in Pat?

**Ask a colleague**

*Finally- if you gave Pat a more potent (stronger) opioid, would her pain be better relieved?*
FURTHER ACTIVITY: Changing opioids

- Find a patient on dihydrocodeine. Using the conversion chart on page 2, calculate how much daily oral morphine they would need.
- Find a patient on morphine. Using the conversion chart on page 2, calculate how much daily subcutaneous morphine they would need.
